Results: Left VA was dominant in 65% of patients. RI values increased and flow decreased with age. Blood flow velocity and volume were higher, and RI was lower in the left than in the right VA. In V1 patients peak systolic velocity and RI were significant higher in V1 segment, and lower in the V2 and V3 segment: $V_{ps}V1=62.7\pm16.4\text{cm/s}; V_{ps}V2=46.5\pm15.1\text{cm/s}; V_{ps}V3=45.6\pm17.7\text{cm/s}; RIV1=72.2\pm10.1; RIV2=68.7\pm12.9; RIV3=64.6\pm14.4$.

Conclusion: The doppler sonographic assessment of extra cranial VA may be useful for the study of hemodynamic changes in patients with vertebrobasilar insufficiency.

28 The Contralateral Carotid Disease In Patients with Internal Carotid Artery Occlusion

Department of Neurology, University Hospital «Sestre milosrdnice», Reference Center for Neurovascular Disorders of Republic of Croatia, Zagreb, Croatia

Aim of the study was to investigate management and natural history of the contralateral internal carotid artery disease in patients with internal carotid artery occlusion (ICAO).

Patients and methods: During one year 296 patients with ICAO were investigated. Retrospective analysis of follow-up examinations was performed, and patients were divided into groups according to contralateral carotid disease. Data are presented as numbers and percentages.

Results: Out of 296 patients, in 90 patients with carotid occlusion only one investigation was performed. Thirty three patients were followed up due to postoperative ICAO. In 14 patients ICAO developed during ultrasonographic follow-up. Contralateraly in this group of patients, 9 had unchanged findings, while in 5 (35.7%) disease progression was observed: in 2 patients from mild stenosis to occlusion, in 1 from mild to subtotal stenosis, in 1 from moderate stenosis to occlusion and in 1 from subtotal stenosis to occlusion. Out of 44 patients with ICAO and contralateral subtotal stenosis at initial investigation, 42 underwent carotid surgery. Postoperatively 32 had normal finding, 6 developed mild carotid stenosis, 2 moderate, and 2 had postoperative carotid occlusion. Two patients were followed up without intervention. Nine patients with bilateral ICAO were followed up during years. Hundred and six patients with ICAO and contralateral mild to moderate changes, were followed-up. The finding was unchanged in 68 patients. In 21 (30%) patients disease progressed to subtotal stenosis, 18 underwent carotid surgery.

Conclusion: In one third of patients with carotid occlusion contralateral carotid disease progression was observed. Further investigations should be conducted.

29 Galen Vein Involvement in a Case of Transient Global Amnesia

The pathophysiology of Transient Global Amnesia (TGA) has been a matter of discussion since years; an attractive hypothesis postulates a cerebral venous drainage impairment, e.g. by identifying a jugular venous valve incompetence, because of the absence of valvular leaflets in the intracranial vessels. We studied a 68 years old previously health patient who came to our attention for the onset of anterograde amnesia since 4 hours and a spontaneously improving course. The urgent brain CT was normal and the ultrasound examination of epiiacic vessels and TCCS was insignificant on the arterial side, but on the venous side it has been found a left jugular valve incompetence on Valsalva maneuver, a markedly angled course of the proximal segment of the Galen vein and a dynamic stenosis of its middle segment during Valsalva maneuver. This finding was highly reproducible in the follow-up at 7 and 40 days and the patient underwent to a neurosonological examination for a right to left shunt, that was positive for a mild shunt. The subsequent diagnostic workup is made by a CTA examination and a MRI – MRA, both negative but not easily performable and valuable in dynamic conditions (like a Valsalva maneuver). This is the second episode of TGA for our patient, being the first ten years before. An amnestic syndrome was described in the Galen vein thrombosis but this is the first report, at our knowledge, of a vein stenosis as responsible of TGA, and neurosonological techniques was demonstrated useful and reliable in dynamic evaluation.

30 A Case of successful Sonothrombolysis Performed on a Carotid T-Type Occlusion

A 66 years woman with a recent diagnosis of idiopathic hypertrophic cardiomyopathy was evaluated because of the onset of a right sided hemiparesis and aphasia since 2 hours (NIHSS 8). The unenhanced brain CT was normal and the neurosonological examination showed indirect signs of left M2
middle cerebral artery (MCA) involvement. The patient under-
went to iv thrombolysis with rtPA with sudden and comple-
ter recovery. After five days there was the abrupt onset of left
side hemiplegia, neglect and hemianopsia. A complete neu-
rosonological evaluation was performed and a right carotid
T occlusion was diagnosed. Then an ultrasound perfusional
examination was made by TCCS with power modulation and
contrast medium bolus injection and a wide hypoperfused
area in the right MCA territory was showed. Because of the
contraindication to the thrombolysis (recent stroke), a rescue
sonothrombolysis was made by repeated boli of contrast me-
dium and continuous TCCS monitoring of the proximal MCA.
During the first five minutes of treatment a rapidly increasing
MCA opening was found and followed by recanalization of
the intracranial ICA. At the same time a disappearance of the
stump flow signal in the right extracranial ICA was registered.
A subsequent perfusional scanning showed a restored micro-
circulation in the right hemisphere and a MRI scan two weeks
later confirmed some small scattered diffusion alteration in
the same territory. TCCS is a simple, rapid and useful tool in
the diagnosis and treatment of acute stroke, even in clinical
situations where there is not time enough for conventional
neuroradiological techniques.

31 US Perfusional Evaluation in Traumatic Brain Injury:
a Clinical Proposal

In order to improve the management of patients with mo-
derate to severe TBI and contusive-hemorrhagic brain lesions
could be useful to achieve perfusional data on the parenchy-
ma around the lesions. This is because a penumbral finding
is likely related to savable tissue and conversely a normal or
luxury perfusion can be predictive of a better prognosis.
We studied four male patients with a TBI (mean age 33.5±22.8
years) and a severe neurological deficit (GCS 5-7) associated
with a multiple contusive-hemorrhagic lesion in the supra-
tentorial zone of a single hemisphere. None of the patient
was eligible to surgery but two of them underwent in the
first week to a decompressive hemicraniectomy. All patients
underwent to a perfusional evaluation with TCCS and power
modulation technique at a mean of 2.3±1.8 days from the
admission to the ICU. A parametric measurement of TP, CBV,
CBF, MTT was performed off line on a short clip stored. Trid-
dimensional parametric maps were also derived and the area of
the perfusion deficit was compared with the correspondent
lesion in the brain CT scan.
A good correspondence was found between the severely
hypoperfused areas in the ultrasound examination and the
contusive-hemorrhagic foci in the brain CT. Patients with
normal perfusional evaluation at the visual and parametric
examination showed a good functional prognosis (mRS 0-
2 at three months).
Methods for perfusional evaluation in the intensive care pa-
tients should be bedside, handle, ease to perform and accu-
rate. Therefore we propose that the ideal method could be a
neurosonological technique.

32 US Perfusion in Space Occupying Brain Lesions
Malferrari G., Zedde M., Dallari A., Nucera A., Servadei F.,

In patients with supratentorial space occupying brain lesions
and an adequate temporal bone window, the evaluation of the
cerebral perfusion with TCCS by second harmonic imag-
ing and second generation contrast media administration,
can help to define the extent and features of the intracranial
processes.
Seven patients (two females and five males, mean age 64 ±
3.56 years) with a histologically confirmed diagnosis of gli-
blastoma multiforme (four patients, two with recurrence), se-
condary brain tumors (from lung cancer, two patients) and an
atypical meningioma (one patient) underwent to a complete
neurological and neuroradiological work-up and to a neuro-
sonological evaluation with TCCS. The ultrasound examination
was made with a power modulation technique and a Sonovue
bolus injection. A short clip was recorded from the visual asse-
ment of contrast medium arrival and it was evaluated off-line
for time and echogenicity measurements. A handy designed
ROI was traced by the guide of single frame examination and
MRI appearance and extent of lesions. The comparison was
made between such a ROI and a contralateral thalamic ROI
(healthy brain tissue) for the echogenicity parameters and
